Comparative structure analysis of Adenylate Kinase

adenelate kinase (ADK) is an important drug target and we would love to know how it works.

We will perform PCA on the complete collection of ADK structures in the protein data-bank (PDB) to reveal detailed features and mechanistic principles of these essential shape changing transitions.

First install the packages needed > Q10. Which of the packages above is found only on BioConductor and not CRAN?

msa

> Q11. Which of the above packages is not found on BioConductor or CRAN?:

Grantlab/bio3d-view

> Q12. True or False? Functions from the devtools package can be used to install packages from GitHub and BitBucket?

TRUE.

Search and retrieve ADK structures

Fetch the query sequence for chain A of the PDB ID 1AKE (example ADK sequence). We will use this to find all ADK structures in the PDB.

```
library(bio3d)
aa <- get.seq("1ake_A")
```

```
Warning in get.seq("1ake_A"): Removing existing file: seqs.fasta

Q13. How many amino acids are in this sequence, i.e. how long is this sequence?

214 amino acids.

Now we can use this sequence as a query to BLAST search the PDB to find similar sequences and structures.

```
  # Blast or hmmer search
  #b <- blast.pdb(aa)
```

```
# Plot a summary of search results
#hits <- plot(b)
```

Let's see what's in `hits` object.

```
#hits$pdb.id
```

Because we do not want to rerun the code above everytime, we just manually spell the `hits` vector

```
hits <- NULL
hits$pdb.id <- c('1AKE_A','6S36_A','6RZE_A','3HPR_A','1E4V_A','5EJE_A','1E4Y_A','3X2S_A','

Color the clusters

rmsd() will calculate all pairwise root-mean-square deviation values of the structural ensemble distance between different structures . This facilitates clustering analysis based on the pairwise structural deviation:

Optional further visualization

we can make a wee movie ("trajectory") of the major difference of ADK.

```
# Visualize first principal component
pc1 <- mktrj(pc.xray, pc=1, file="pc_1.pdb")
```
